

Teacher guide

Teacher guide: use the responses as evidence criteria and discussion support. Confirm the actual supplied kit, current school SOP, teacher demonstration, approved products and submission requirements. The workbook records learning; it does not authorise practical work.

Page 3 • Write one product criterion and one piece of process evidence that would help you judge it.

Example: The timber to metal join should feel flush. A stopped work inspection photo and caption can identify the reference used, the check completed and any teacher directed correction.

Page 4 • Read the guide as a sequence

Example: the guide controls preserving the witness line and the broad making sequence; the supplied kit controls component identity and the mechanism's required fit, while the school procedure controls the local setup. A photograph may be resized and cannot establish a missing measurement or authorise operation.

Accept two distinct source roles. Students should recognise that written facts and local authorisation answer different questions. Do not turn the starting stock requirement into a final barrel dimension.

Page 5 • Control the risk before rotation

Example: rotating work is the hazard; loose hair becoming caught creates a risk of serious injury. Securing hair under the approved procedure and completing the supervised pre start check help prevent the event. Accept another specific hazard with a credible event or consequence and a matching control.

The control should address the event, not merely repeat "be careful". PPE alone is insufficient for a hazard caused by incorrect workholding or uncertainty about setup.

Page 6 • What is the strongest next action when applying "Understanding the Pen project brief and success criteria"?

B. Before each project stage, check the approved instructions, identify the intended quality outcome and record evidence of my decision or result.

Before each project stage, check the approved instructions, identify the intended quality outcome and record evidence of my decision or result.

Page 6 • Which evidence would best demonstrate this learning in the Pen folio?

D. Record the marked timber, paired grain alignment, identified kit parts and completed checks as progressive Pen project evidence.

Record the marked timber, paired grain alignment, identified kit parts and completed checks as progressive Pen project evidence.

Page 6 • Which statement best captures the main idea in "Managing wood lathe hazards, risks and teacher approval"?

A. Effective safety on the lathe comes from identifying hazards and applying the strongest practical controls before relying on PPE.

Effective safety on the lathe comes from identifying hazards and applying the strongest practical controls before relying on PPE.

Page 6 • A student has a polished pen but no record of preparation or safety checks. Explain what is missing and what evidence should be collected during the next project.

The product alone does not demonstrate the whole brief. Collect authentic sketches, verified cutting information, WMS, flowchart, stage checks and captioned decision evidence progressively, then evaluate with PMI. Do not fabricate past approvals.

Page 7 • Choose sound timber first

You can report an attractive pattern and a dark line at a stated location. You cannot yet assert that it is harmless grain or a split. Inspect the faces and end under suitable conditions and obtain teacher confirmation of soundness and adequate starting stock before proceeding.

The response should separate observation from diagnosis and retain the guide's starting stock boundary. Accept another careful description of the same uncertainty.

Page 8 • Keep the grain relationship visible

Reversing a piece can interrupt the direction or continuation of the visible figure across the pair. Mechanical fit and grain continuity are different criteria. Check the witness line, recorded grain order and teacher approved arrangement before continuing.

Students should distinguish a functioning assembly from a resolved visual relationship. No claim of an invisible or perfectly continuous seam is required.

Page 9 • Record one value that is known, one value needing confirmation, and one sensible way to manage an offcut.

Known: current guide starting blank at least 110 × 20 × 20 mm. Confirm: actual barrel cutting lengths or bit size. Offcut: retain suitable clean material in the approved reuse system; contaminated waste follows local product and school controls.

Page 10 • What is the strongest next action when applying "Selecting and inspecting timber for the Pen blank"?

B. Inspect the starting timber carefully, record what you observe and confirm suitability with the teacher before use.

Inspect the starting timber carefully, record what you observe and confirm suitability with the teacher before use.

Page 10 • Which evidence would best demonstrate this learning in the Pen folio?

D. Show the original orientation mark, the corresponding lines on the paired parts and the final grain continuity judgement.

Show the original orientation mark, the corresponding lines on the paired parts and the final grain continuity judgement.

Page 10 • What is the strongest next action when applying "Planning responsible material use and the Pen cutting list"?

B. Record only approved values, confirm uncertainties with the teacher and plan how the timber will be used efficiently.

Record only approved values, confirm uncertainties with the teacher and plan how the timber will be used efficiently.

Page 10 • Two barrels came from one blank, but the grain looks disconnected. Give two possible causes and explain how you would investigate without guessing.

A barrel may be rotated, reversed or mixed with another pair. Compare the original witness line and progressive photos, keep the pieces together and ask the teacher to confirm orientation before further processing.

Page 11 • Make references you can trust

A witness line records orientation and the relationship of the paired grain. A dimensional mark records a verified size or position. If the witness line becomes unclear, stop, preserve the pieces and check the original record and teacher approved reference rather than guessing.

The answer should identify the different information carried by each mark. Do not accept the claim that a lengthwise witness line supplies the final barrel length.

Page 12 • Prepare the brass tubes for bonding

The outer surface meets the adhesive and needs the approved abrasion and cleanliness for bonding. Adhesive inside the bore may interfere with later components, while damaged or distorted ends can affect fit and preparation. The tube must retain its intended form.

Credit the distinction between bonding contact, internal clearance and undamaged geometry. Do not require a particular abrasive grade, cleaner or adhesive product.

Page 13 • Drill through the end grain

Safety: secure workholding helps prevent the blank moving or spinning unexpectedly. Quality: it maintains the approved position and alignment so the hole follows the intended direction for the tube. The exact clamping arrangement requires teacher confirmation.

The answer should connect one control to two distinct benefits. Hand pressure alone is not accepted as the approved workholding method.

Page 14 • What is the strongest next action when applying "Marking the Pen billet and preserving reliable references"?

B. Apply and protect the centre/grain line, keep paired parts identified and confirm markings with the approved source and teacher.

Apply and protect the centre/grain line, keep paired parts identified and confirm markings with the approved source and teacher.

Page 14 • Which evidence would best demonstrate this learning in the Pen folio?

D. Show both prepared sleeves and explain the identification, surface quality and teacher checks completed before bonding.

Show both prepared sleeves and explain the identification, surface quality and teacher checks completed before bonding.

Page 14 • What is the strongest next action when applying "Drilling clean Pen blank holes and clearing swarf"?

B. Use the teacher approved setup, clear swarf as demonstrated and stop for approval whenever the process appears abnormal.

Use the teacher approved setup, clear swarf as demonstrated and stop for approval whenever the process appears abnormal.

Page 14 • Match each check to the problem it helps prevent: protect the witness line; prepare tube exteriors; clear swarf by the approved method. Explain one link in detail.

Witness line: loss of paired orientation. Tube exterior preparation: poor bonding from unsuitable surface condition. Swarf clearance: restricted chip removal, friction and poor hole quality. Explanation should connect the named action to the actual later stage, not claim that one check guarantees success.

Page 15 • Explain why identifying every component is necessary but does not prove that a mandrel assembly is ready to run.

Identification confirms the intended kit parts are present. Readiness additionally requires correct order and fit, sound clean components, appropriate support, secure workholding, clearance and teacher approval under the current SOP.

Page 16 • Mount the pair in grain order

Counting checks that expected parts are present but does not establish their identity, condition, correct kit order, aligned grain relationship or secure mounting. These checks and teacher authorisation are still required before starting.

Accept a selection of relevant checks provided the response distinguishes inventory from verified setup. Do not supply an invented tightening value or order from a different kit.

Page 17 • Make the pre start check deliberate

A stopped lathe is stationary but may still be capable of starting. Isolation, confirmed through the school procedure, prevents starting while the permitted adjustment or inspection takes place. The student must verify the required state and teacher directions rather than infer it from silence or lack of motion.

Credit the distinction between motion and prevention of starting. Do not accept an invented isolation method; the current local procedure controls it.

Page 18 • What is the strongest next action when applying "Understanding between centres turning and the approved Pen mandrel"?

B. Follow the approved Pen mandrel process, align the grain reference and obtain teacher approval before and during turning.

Follow the approved Pen mandrel process, align the grain reference and obtain teacher approval before and during turning.

Page 18 • Which evidence would best demonstrate this learning in the Pen folio?

D. Photograph the clean staged components, the three collets and brass thumb screw, aligned timber parts and completed teacher checkpoint.

Photograph the clean staged components, the three collets and brass thumb screw, aligned timber parts and completed teacher checkpoint.

Page 18 • What is the strongest next action when applying "Lathe pre start checks and secure approved workholding"?

B. Isolate, inspect all required controls, confirm workholding and obtain teacher approval before starting.

Isolate, inspect all required controls, confirm workholding and obtain teacher approval before starting.

Page 18 • At pre start you notice an unexplained gap and a grain line that no longer matches. Record your decision, who must check it and what would count as evidence of a resolved problem.

Keep the machine isolated as required by the SOP, stop and tell the teacher. Do not guess a spacer arrangement or tightening correction. Evidence records the observed gap/orientation issue, teacher directed resolution, recheck and actual approval.

Page 19 • Move from square to cylinder

Changes in the actual form show whether the intended material removal has occurred. Time alone does not reveal remaining flats, uneven areas or excessive removal, and timber or process conditions may differ. Inspection at approved stops allows a controlled decision.

Students should use an observable quality indicator rather than imply that all blanks need the same turning time.

Page 20 • Notice how the tool action changes the surface

Both actions can have an approved purpose, and the result depends on the task stage, timber response, setup and correct presentation. The student should compare the observed result with the intended purpose and follow teacher direction rather than rank one action as universally better.

The answer should recognise context and controlled observation. No tool angle, bevel technique or machine setting is required.

Page 21 • Check the profile before removing more

Example: profile comparison checks proportion and the transition to the actual bush or kit reference; grain order comparison checks whether the paired bodies still correspond. Also accept authorised dimension, symmetry or surface checks if their distinct purposes are explained.

The answer should distinguish smoothness from at least two other meaningful criteria. Do not invent numerical tolerances or recommend matching an over reduced part by removing extra timber elsewhere.

Page 22 • What is the strongest next action when applying "From square blank to controlled cylindrical form"?

B. Follow the approved process, pause at checkpoints and compare both Pen bodies before further material is removed.

Follow the approved process, pause at checkpoints and compare both Pen bodies before further material is removed.

Page 22 • Which evidence would best demonstrate this learning in the Pen folio?

D. Use checkpoint photos and notes to show observed surface changes, teacher checks and decisions made during Pen turning.

Use checkpoint photos and notes to show observed surface changes, teacher checks and decisions made during Pen turning.

Page 22 • What is the strongest next action when applying "Monitoring profile, alignment and material removal against approved kit references"?

B. Pause regularly to compare the work with approved references and seek teacher approval before further material removal.

Pause regularly to compare the work with approved references and seek teacher approval before further material removal.

Page 22 • Complete the reasoning chain: I notice an uneven area → I check... → I decide... → I record... . Explain why another unplanned cut could make it worse.

Check the stopped work against the approved profile, paired orientation and teacher guidance; decide on the authorised next action; record observation, reference, teacher advice and outcome. Extra removal cannot replace lost timber and may deepen imbalance or compromise the kit transition.

Page 23 • Read the surface before sanding

Example: I can see a narrow scratch beside an even surface. It may have come from handling, but this is unconfirmed. I would stop, inspect the clean surface and surrounding profile in suitable light, and ask the teacher to confirm the cause and permitted response.

Separate observation from inference. Accept another plausible cause if it is explicitly uncertain. The next step must investigate the defect and protect the established profile, not automatically sand more.

Page 24 • Refine in stages

A fine abrasive may refine only the shallower surface while the earlier scratch remains. Prolonged sanding can remove unnecessary timber or round the ends, changing the intended profile. The maker should review the approved sequence and inspect between stages.

The answer should link the purpose of each stage to scratch refinement and explain the consequence of uncontrolled extra material removal. Do not require invented grit numbers or sanding times.

Page 25 • Choose a finish from evidence

Example: the label identifies the approved product and its intended use or application directions; the SDS identifies its hazards and controls. Also accept the school SOP for local requirements and the demonstration for applying them, provided the two roles are clearly distinguished.

Students should use complementary sources rather than treating one glossy result as proof of suitability. No particular product, PPE combination, coat count or curing time is prescribed by this task.

Page 26 • Question 1 • Diagnosing tool marks and surface defects before sanding

B. Stop, inspect under suitable lighting, describe the defect and seek teacher approval before any correction or sanding.

Stop, inspect under suitable lighting, describe the defect and seek teacher approval before any correction or sanding.

Page 26 • Question 2 • Using a progressive approved abrasive sequence

B. Follow the approved sequence, inspect between stages and stop when the intended surface condition is achieved with teacher approval.

Follow the approved sequence, inspect between stages and stop when the intended surface condition is achieved with teacher approval.

Page 26 • Question 3 • Selecting and applying the approved Pen finish from product information

D. Provide before and after photos with notes on product identification, surface checks, teacher approval and final appearance and protection.

Provide before and after photos with notes on product identification, surface checks, teacher approval and final appearance and protection.

Page 26 • Surface and finish check • applied task

A defensible sequence is: inspect and diagnose the turned surface; follow the approved progressive abrasive sequence with inspections; apply the approved finish to the accepted prepared surface; confirm the product directed curing/handling condition before assembly. Teacher directed correction may loop back to inspection.

The sequence tests dependencies rather than an invented operating method. Accept equivalent wording and a justified feedback loop. The crucial condition is approved readiness to handle the finish, not shine alone.

Page 27 • Keep one complete kit together

Keep the uncertain part separate from the verified matched kit, preserve the clean staging arrangement and compare the components with the current kit instructions and teacher guidance. Do not select a part merely because it looks similar or try to force a fit.

The response must maintain kit identity and seek verification before a difficult to reverse operation. A photograph can record the issue but cannot identify an unverified part by itself.

Page 28 • Press squarely and protect the timber

The component is tilting and resistance has increased. Extra pressure could worsen misalignment, damage the kit or mark/split the finished body. Stop, keep the setup safe and obtain a teacher inspection before any correction or continuation.

Credit observation, consequence and a controlled stop. Do not accept an unapproved attempt to reverse or straighten a pressed component. No force or tolerance value is required.

Page 29 • Test as the mechanism advances

The joint's appearance reveals alignment and surface condition but does not establish the mechanism's correct depth or the refill's extension. Incremental pressing with the kit specified functional check helps prevent overpressing before it becomes difficult to correct.

The answer should distinguish visual evidence from functional evidence and connect testing to the possibility of irreversible damage. Do not invent an insertion depth.

Page 30 • Question 1 • Identifying and staging the Pen kit components for assembly

B. Compare the staged timber bodies, clip/button and nib shroud with the approved resource and stop for any uncertainty.

Compare the staged timber bodies, clip/button and nib shroud with the approved resource and stop for any uncertainty.

Page 30 • Question 2 • Assembling the clip/button and nib shroud in the approved sequence

B. Follow the kit resource and teacher demonstration, support the finished bodies and stop whenever alignment or resistance is uncertain.

Follow the kit resource and teacher demonstration, support the finished bodies and stop whenever alignment or resistance is uncertain.

Page 30 • Question 3 • Preventing misalignment and damage during Pen assembly

D. Record clean staging, alignment checks, teacher approvals and any stop and report decisions that prevented damage.

Record clean staging, alignment checks, teacher approvals and any stop and report decisions that prevented damage.

Page 30 • Assembly decisions • applied task

Example: After the small adjustment, I cannot confirm that the refill extension matches the kit requirement. I stopped further pressing and asked the teacher to check the mechanism position and direct the next action.

Accept any honest observation consistent with the hypothetical case. The decision must withhold further force until the uncertainty is resolved; it must not invent a diagnosis, depth or repair.

Page 31 • Design for the hand and the eye

Example: I would compare the fullness near the grip in two sketches. I would judge its visual balance with both barrels and the kit, then use teacher confirmed feasibility and later user feedback about control and comfort. Accept transitions or grain continuity where the two judgement methods are explicit.

The response should connect a particular feature to both appearance and function. Do not require a numerical size or a claim that one profile suits every hand.

Page 32 • Build quality into the process

Example: At the assembly staging checkpoint, I compared the two barrel grain references with their intended order and observed that the marks corresponded before pressing. This is a model of a specific record, not a claim about the student's actual work. Accept any source grounded stage, criterion and observable result.

A strong record reveals what was judged and what was seen. Teacher approval should be recorded only if it happened; students should not invent a pass or compliance claim.

Page 33 • Compare ways of making

Example: the approved mandrel supports and locates the paired bodies. The maker and teacher still check grain order, secure setup or whether the developing profile meets the agreed criterion. Accept another demonstrated workholding example with the roles clearly separated.

Students should explain assistance rather than automation of judgement. No machine setup or industrial programming method is required.

Page 34 • Question 1 • Designing a comfortable and visually resolved Pen profile within kit constraints

B. Compare profile sketches, check feasibility with the teacher and monitor the developing form against the selected design.

Compare profile sketches, check feasibility with the teacher and monitor the developing form against the selected design.

Page 34 • Question 2 • Standards, quality control and production techniques in Pen manufacture

B. Use a check–decide–act cycle at each Pen stage and obtain teacher approval whenever the result is uncertain.

Use a check–decide–act cycle at each Pen stage and obtain teacher approval whenever the result is uncertain.

Page 34 • Question 3 • Comparing handcraft, jigs and repeat production technologies

D. Create a comparison table showing handcraft, jigs and repeat production in terms of control, consistency, adaptability and responsibility, supported by examples from the Pen project.

Create a comparison table showing handcraft, jigs and repeat production in terms of control, consistency, adaptability and responsibility, supported by examples from the Pen project.

Page 34 • Design and production check • applied task

Handcraft uses disciplined observation and repeated comparison. Approved workholding stabilises or locates parts in repeatable conditions. Repeat production standardises setup and operations across many items. All require accurate initial setup and ongoing human responsibility for checking and responding to problems.

Accept equivalent comparisons. The common responsibility must be explicit; do not accept “machines make mistakes impossible” or a claim that a mandrel replaces judgement.

Page 35 • Write a WMS that guides work

Example: during drilling, an inadequately secured blank could move or spin, causing impact injury or damage. The approved clamping/workholding arrangement and supervised setup check address this; the teacher demonstration and school drilling SOP confirm the actual controls. Accept another specific stage with a coherent cause and effect chain and a verified source.

The control must address the described event. The example is a planning response, not permission to operate. Do not assign an invented risk score or treat PPE alone as a complete control system.

Page 36 • Map inputs, processes and outputs

Example: an identified blank and approved marking information are inputs; marking and the approved cutting stage are the processes; the intended output is the identified pair of barrel pieces, with offcut or cutting debris as another locally applicable output. Accept another genuine stage, including information or evidence outputs, if the distinctions are clear.

An input enters or enables a stage, the process is an action, and an output results from it. Students should not guess a material or waste stream that did not occur locally.

Page 37 • Explain benefits and trade offs

Example: accurate marking reduced avoidable offcut waste compared with my earlier layout; the two labelled sketches or a real offcut record support this. It does not establish the source timber’s certification or the entire pen’s life cycle impact. Accept another verifiable, bounded claim; hypothetical evidence must remain labelled as proposed.

A useful answer links claim to evidence and an honest limit. Reject unsupported sourcing, recyclability, toxicity or lifespan claims.

Page 38 • Question 1 • Building a real Pen Work Method Statement

D. Submit the completed WMS with dated checkpoints and records showing that the stated controls were actually used and reviewed.

Submit the completed WMS with dated checkpoints and records showing that the stated controls were actually used and reviewed.

Page 38 • Question 2 • Creating the Pen production flowchart: inputs, processes and outputs

B. Map each approved Pen stage with its inputs, process, output, checkpoint and relevant impact, then verify the sequence with the teacher.

Map each approved Pen stage with its inputs, process, output, checkpoint and relevant impact, then verify the sequence with the teacher.

Page 38 • Question 3 • Explaining social and environmental impacts of Pen production and use

B. Use the flowchart and project records to identify one social benefit, one environmental impact, one uncertainty and one realistic improvement.

Use the flowchart and project records to identify one social benefit, one environmental impact, one uncertainty and one realistic improvement.

Page 38 • Plan and impact check • applied task

Add “Does the prepared surface meet the approved readiness criterion?” Yes leads to the approved finishing stage after its checkpoint. No leads to teacher directed inspection or an authorised correction, then reinspection before the decision is tested again.

The answer needs two labelled outcomes and a genuine feedback route. A no branch must not prescribe unverified sanding grades, extra force or another improvised fix.

Page 39 • Photograph a decision, not just a result

Example: photograph the grain reference arrangement before mounting at an approved stopped checkpoint. Use a view showing both bodies and their corresponding marks; explain the decision to continue only after the alignment check. Accept another meaningful stage, a suitable view and a decision it can actually evidence.

The photograph must be safe, purposeful and linked to authentic work. It cannot prove supervision or safe operation without supporting records.

Page 40 • Evaluate with Plus, Minus and Interesting

Example: the grain appears to change as the blank becomes cylindrical. Existing progressive photographs could support the observation; a proposed comparison of the marked blank and turned bodies would help investigate it. Accept comfort, staging, impact or process findings if they are questions/discoveries rather than unsupported praise.

Interesting is not a spare Plus column. The answer should distinguish an observation or question from a proven explanation and name suitable evidence.

Page 41 • Check the story and transfer a skill

Example: my labelled paired body photographs show how I maintained matching references. In a later timber assembly, I would use the new project’s approved part identification method, then check that every intended pair or joint still corresponds before assembly. Accept another evidence based skill and a specific future verification.

The response must connect actual evidence, a transferable principle and a meaningful future check. It must not claim universal expertise or carry pen kit settings into another project.

Page 42 • Question 1 • Photographing Pen stages and explaining problem solving

B. Photograph approved stop points and explain each important image using observation, decision, action and result.

Photograph approved stop points and explain each important image using observation, decision, action and result.

Page 42 • Question 2 • Using PMI to evaluate the completed Pen

D. Use final inspection notes, staged photographs, user judgement, teacher checkpoints, WMS records and impact observations to support the PMI.

Use final inspection notes, staged photographs, user judgement, teacher checkpoints, WMS records and impact observations to support the PMI.

Page 42 • Question 3 • Final reflection, evidence review and skill transfer

B. Audit your folio, fix gaps, link evidence to outcomes and write one concise improvement and transfer statement.

Audit your folio, fix gaps, link evidence to outcomes and write one concise improvement and transfer statement.

Page 42 • Evidence and reflection check • applied task

Hypothetical example: the final twist test showed smooth action and the labelled assembly photograph showed even joins, supporting the functional and alignment criteria. Next time I would record the pre press orientation checkpoint more clearly so the sequence is easier to trace.

Accept another specific, balanced caption with a criterion, genuine or clearly hypothetical evidence and a checkable next step. Reject an invented perfect result or evidence the student cannot substantiate.

Page 44 • Kit name / supplier reference / instruction version and the teacher confirmed source of my cutting information:

Student supplies the actual kit identity and a traceable instruction or teacher source. Do not substitute the illustrated example for local confirmation.

Page 44 • Explain one kit constraint that affected your plan, and one material use decision you made.

A specific constraint such as confirmed tube/barrel information or interface requirements is linked to a planning decision. Material reasoning should identify a real action, such as preserving pairing or retaining suitable offcuts through the workshop system.

Page 45 • Idea A • annotated freehand sketch

An understandable freehand pen profile with labels for grip, grain relationship and kit interfaces. Exact dimensions should only appear when supported by actual approved kit information.

Page 45 • Idea B • annotated freehand sketch

A meaningfully different profile, with the same kit constraints and clear labels. Do not credit an unsupported invented component or dimension as an approved design.

Page 45 • Choose an idea. Explain one comfort advantage, one manufacturing challenge and the information you need before approval.

A justified choice links comfortable handling and appearance to an achievable approved process, identifies a genuine challenge such as consistent transitions, and names a kit or teacher confirmation still needed.

Page 46 • Complete the table for your actual project. Use stage specific controls and identify the relevant school SOP.

A complete WMS follows the actual approved sequence, identifies hazard event consequence relationships, describes workable higher order controls with supporting procedures/PPE, cites local SOP and identifies genuine teacher hold points. Blank or generic “be careful” controls need correction before work.

Page 46 • Which hazard needs the strongest control in your plan, and why?

Accept a reasoned project specific judgement: rotating work could catch a loose item, so secure personal items, verified workholding and isolation/clearance procedures are needed before operation. PPE alone does not prevent entanglement.

Page 47 • Draw your Pen flowchart. Include information, materials, equipment and skill inputs, the actual stages, outputs and at least one feedback loop.

A connected process uses the approved sequence and accounts for materials, kit information, equipment, time and skill; outputs include pen, records and waste. The decision has meaningful Yes/No branches and a controlled recheck path. Arrows must not imply unauthorised machine action.

Page 47 • Explain one social effect and one environmental effect of a decision in your flowchart. State what evidence would support each claim.

Social: safe organised shared equipment use may reduce disruption, supported by actual routines or time records. Environmental: planned stock use may reduce offcuts, supported by measured or observed waste. Qualified explanations are stronger than unsupported “eco friendly” claims.

Page 48 • Complete the record with four significant stages. Continue on an attached page when required.

Records should identify real stages, useful observations, approved actions and outcomes, and traceable photos or notes. Judge authenticity and causal explanation. Do not accept reconstructed teacher signatures, copied sample photos or claims unsupported by the record.

Page 48 • Choose one evidence item. Write a caption explaining what you checked, what changed and what happened next.

An effective caption names the stage and specific feature, cites the reference or teacher advice, explains the decision/action and reports the actual outcome. “I finished turning” alone does not explain learning.

Page 48 • Name one problem you investigated rather than guessed at.

A genuine symptom, evidence based or teacher confirmed cause and authorised response. An unresolved problem is acceptable if honestly identified and followed by the correct next check.

Page 49 • Complete Plus, Minus and Interesting with evidence and a reason.

Plus states an observed strength and why it meets a criterion. Minus identifies a limitation, likely or confirmed cause and effect without inventing certainty. Interesting records a discovery or question that can inform a later project. Every judgement links to evidence.

Page 49 • Propose one practical improvement. Explain how it addresses a cause you identified.

A feasible next project change targets the stated cause, such as earlier orientation checks if pairing was lost. “Try harder” does not identify a useful process change.

Page 49 • What skill will you transfer to another timber project? Explain how the new context might change the procedure.

A principle such as source verification, quality checkpoints, grain observation or evidence captions transfers. The learner must recognise that new workholding, kit details or machine methods require fresh local instruction and approval.

Page 50 • Add a page, photo or file reference for each evidence area. Resolve any missing item with your teacher.

Check that all twelve source folio purposes are represented by authentic traceable evidence. Missing items remain visible; do not award completion because the checklist alone is filled in. Submission requirements and assessment judgement come from the teacher.
